Keeping the Customers Worth Keeping

A data-driven retention proposal for Company A · Proof of Concept

Shafayet Jamil
GCI World 2026 · Final Assignment

Executive summary

Broad retention offers lose money — a targeted, value-based programme makes it profitable

1

The problem

Customers leave in a saturated market. Company A cannot tell who will leave, so retention money is spent blindly.

2

What the data shows

Churn rises sharply with ageing handsets (>1 year), falling usage, and the 11–12 month contract end.

3

What we built

A churn-risk score (LightGBM model). It ranks customers correctly 70% of the time (ROC-AUC 0.70).

4

What we propose

Each month, contact only customers whose expected saved profit beats the offer cost, with an offer that fits their reason to leave.

80.6% vs 17.8%

churn in the model's top-10% vs bottom-10% risk group

−$4.09M

per year if we give everyone an offer

+$0.13M / yr

with our targeted rule (ROI 0.64), base case

Source: Company A data (100,000 customers), own analysis. Profit on a 100k-customer base at a realistic 2% monthly churn; assumptions on slide 13.

Why churn matters in mobile telecom

Growth now means keeping customers, not finding new ones

5.6 bn

unique mobile subscribers worldwide (end-2023) — about 69% of people. The market is saturated. [3]

5–25×

more expensive to win a new customer than to keep an existing one. [2]

+25–95%

profit increase linked to a 5-point rise in customer retention. [1]

What this means for Company A

- Every lost customer must be replaced by taking one from a competitor — at a much higher cost.
- Handset upgrades and new technology (5G) are moments when customers compare operators [4].
- Research shows churn can be predicted from usage, billing and handset data — and that the value comes from the campaign it drives, not the model itself [5][6].

Sources: [1] Reichheld & Schefter 2000; [2] Gallo 2014 (HBR); [3] GSMA Mobile Economy 2024; [4] Ericsson Mobility Report; [5] Verbeke et al. 2012; [6] Neslin et al. 2006.

The data at a glance

100,000 customers, 100 facts each — rich, but with gaps and one trap

100,000

customers

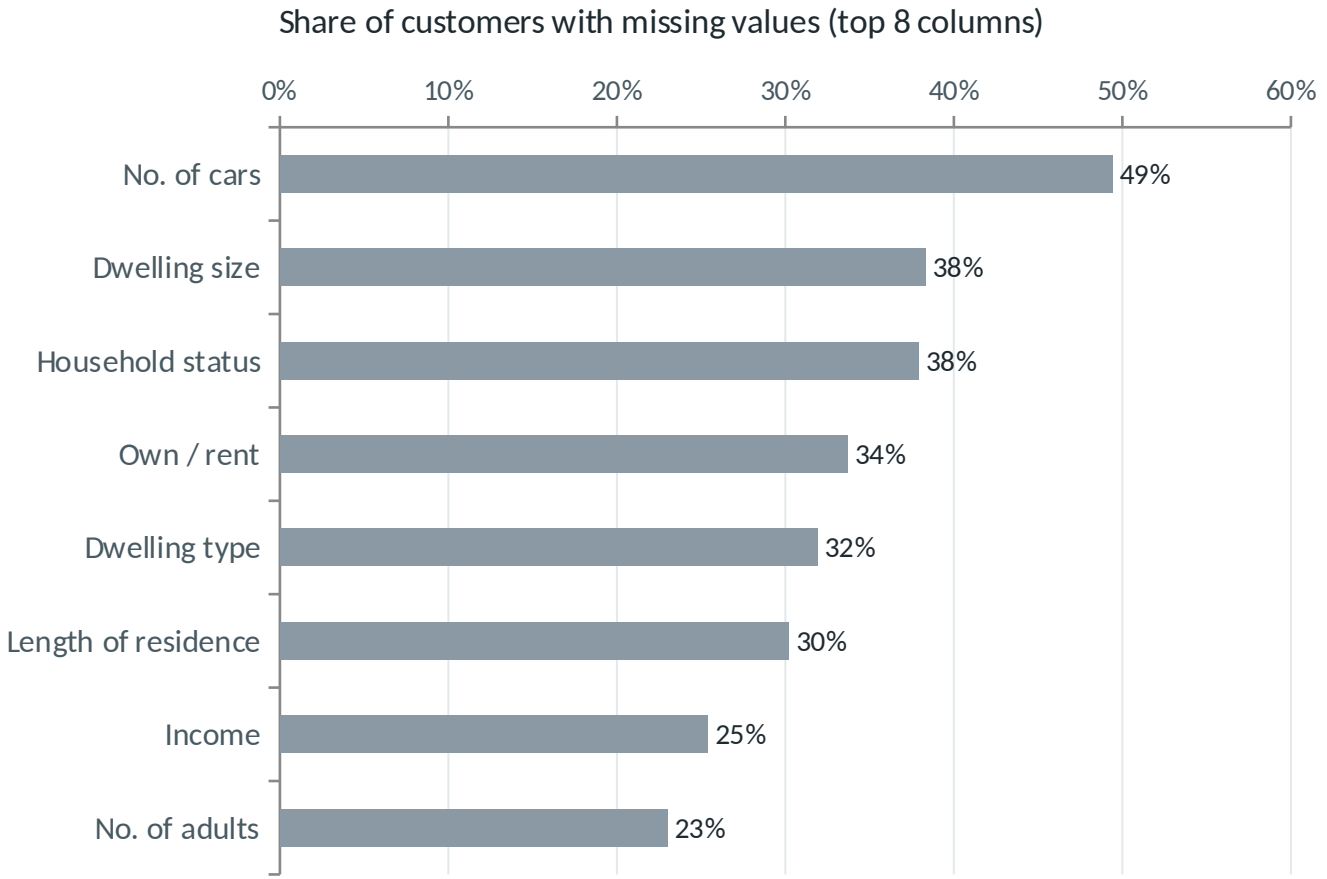

100

columns: usage, billing, handset, household

2 tables

joined 1-to-1 on Customer ID

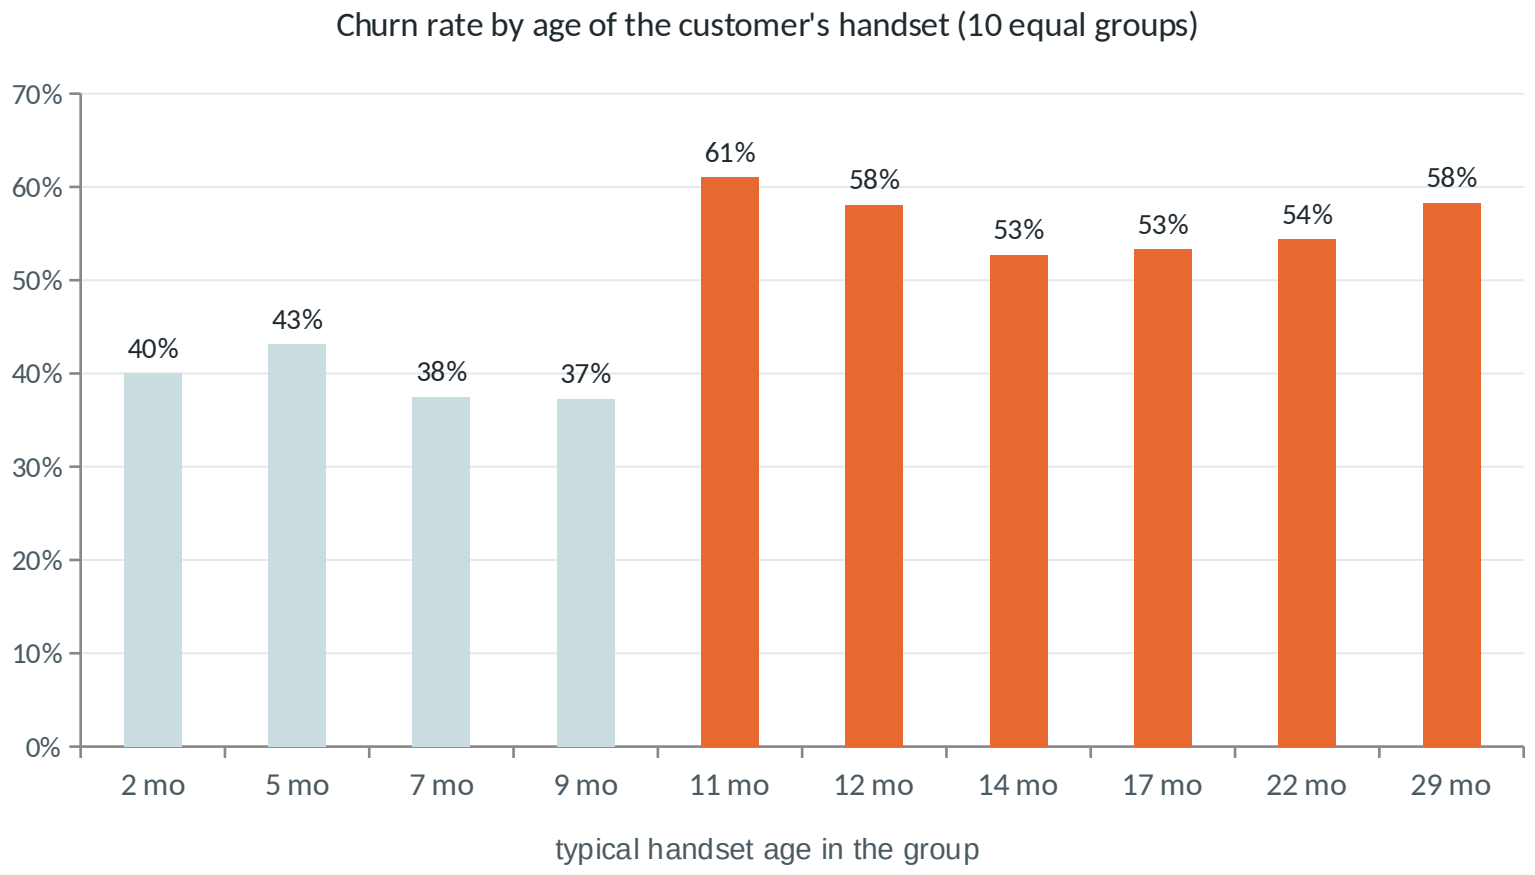

Watch out: 50% of these customers churned, but a real operator loses ~2% a month. The sample was balanced on purpose, so we correct for it in the business case.

Source: Company A data. Missing values are mainly third-party household data; usage and billing data are almost complete. Gaps were kept, not deleted.

Old handsets are the clearest warning sign

After about one year, churn jumps from ~40% to ~55–60%

What it means

- Customers with a handset older than ~11 months are about 1.5× more likely to leave.
- That is when rivals' new-phone deals look most attractive.
- Cheaper and refurbished handsets also churn more (57% vs 36% for the cheapest vs most expensive).
- **Lever: a timely upgrade offer.**

Source: Company A data, own analysis. Each bar = 10% of customers, ordered by handset age.

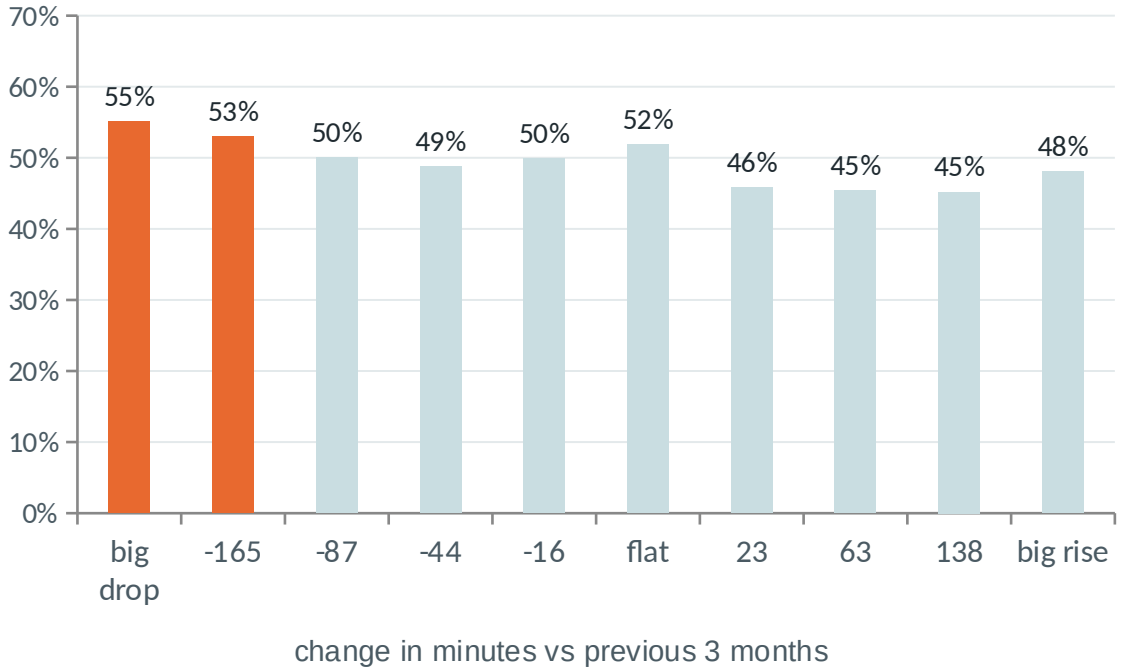

Contract end and falling usage signal departure

Risk peaks at month 11–12, and customers use us less before they leave

Churn rate by months as a customer

Churn rate by change in monthly minutes (10 groups)

Month 11: 65% churn — right as one-year contracts end. Act before month 10.

Usage drop = early warning: 55% churn vs 45% when usage grows.

Source: Company A data, own analysis.

From findings to a clear question

Four ideas tested — three confirmed and turned into one prediction task

What we expected → what the data said

Old handsets drive churn	**Confirmed**	~40% → ~58% after 1 year
Falling usage is an early warning	**Confirmed**	55% vs 45% churn
Contract end concentrates risk	**Confirmed**	65% at month 11
Poor network quality drives churn	**Not supported**	Dropped calls barely matter

The question for the model

Target: will this customer leave in the next 31–60 days? (yes / no)

Why this target: it is linked to levers we can pull, and leaves one month to act.

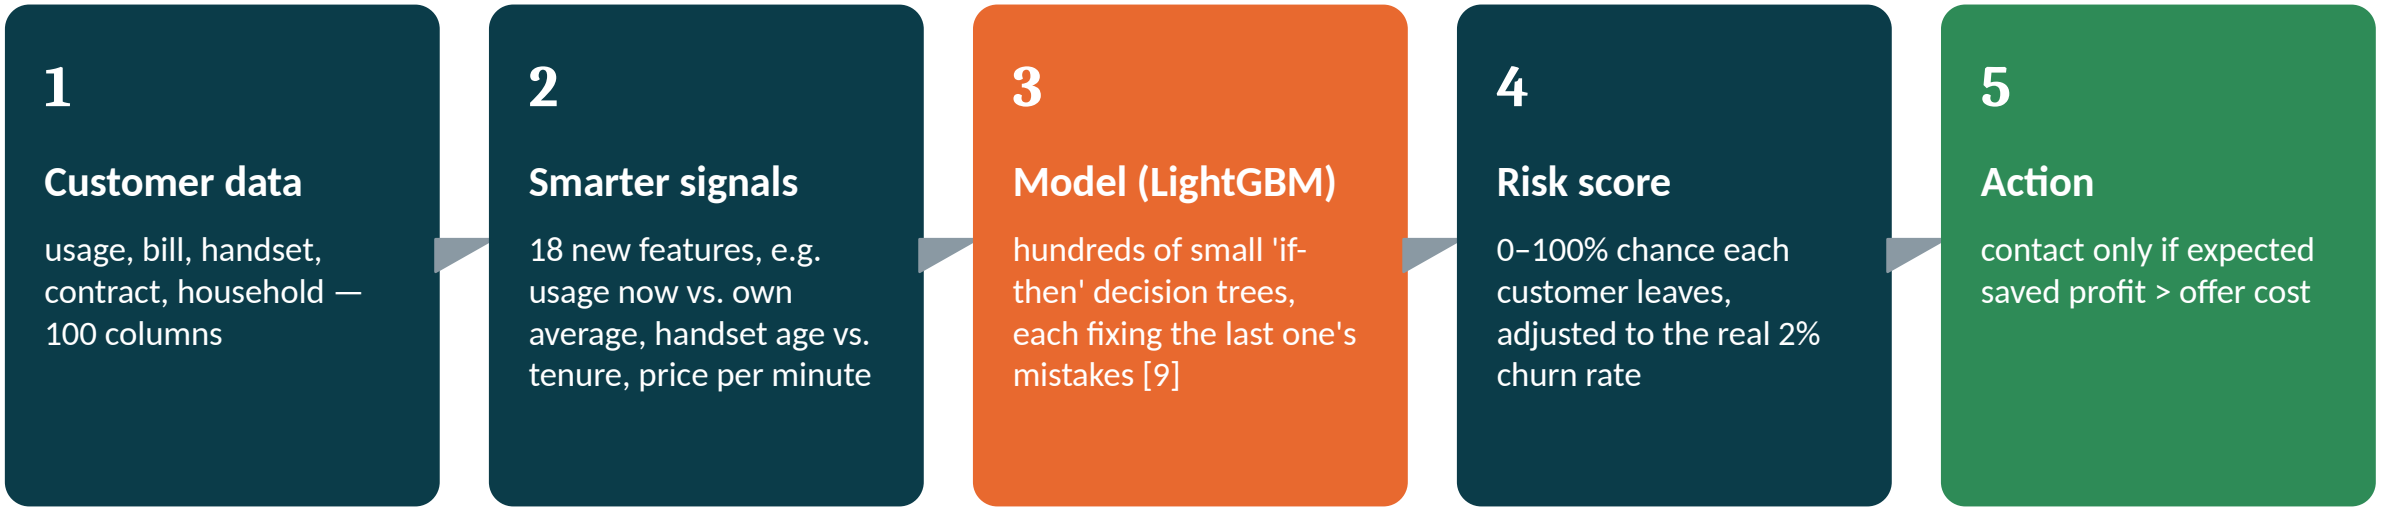

How we score the model: ROC-AUC — how often it ranks a real leaver above a stayer (0.5 = coin toss, 1.0 = perfect). Plus accuracy.

How we score the business: net profit of the retention campaign [5].

Source: own analysis. [5] Verbeke et al. 2012 — profit-driven evaluation of churn models.

How the churn-risk score works

Many small decision rules, combined, turn 118 facts into one risk score per customer

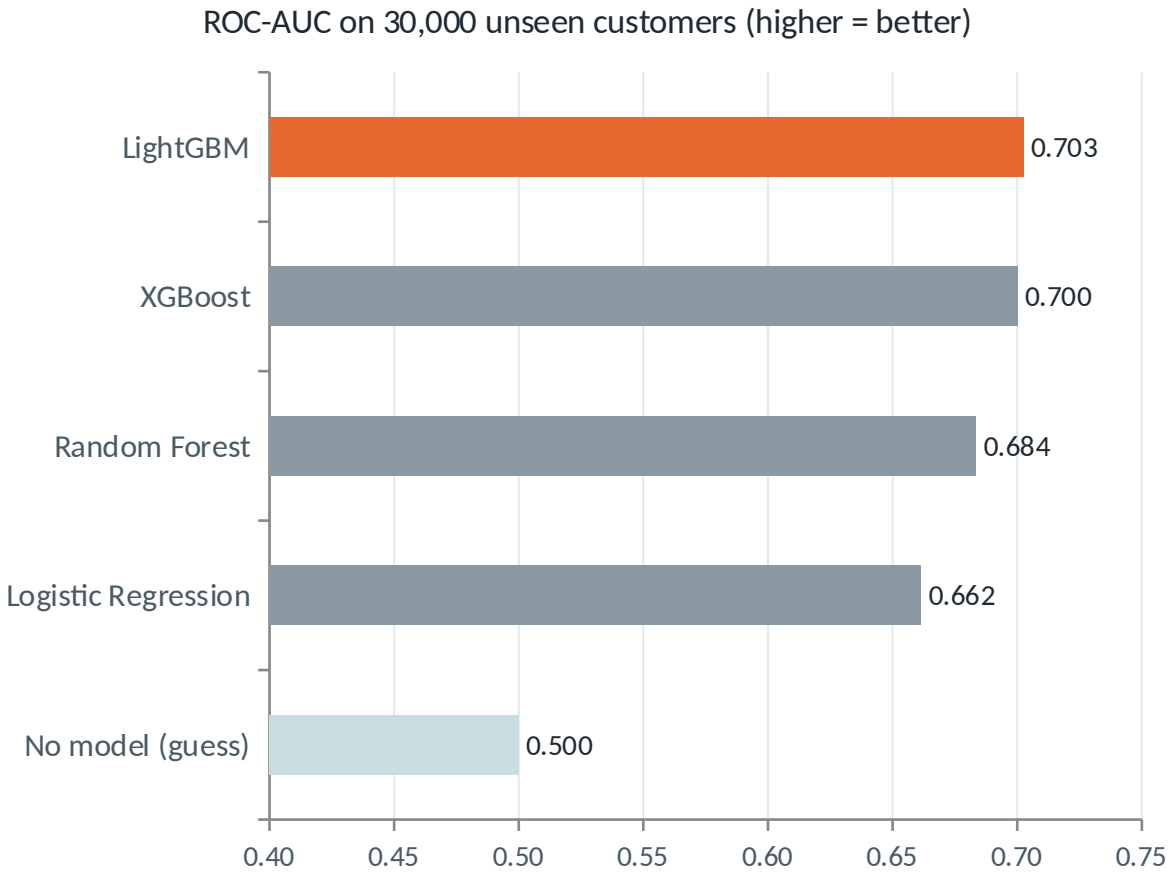

Why this approach

- Tree-based models handle mixed data, missing values and extreme values without manual fixes — exactly what this data has.
- Tested fairly: trained on 70% of customers, scored once on the other 30% it never saw, and checked 5 times on different splits (cross-validation).

Methods: [7] scikit-learn; [8] XGBoost (Chen & Guestrin 2016); [9] LightGBM (Ke et al. 2017); [10] Random Forest (Breiman 2001).

LightGBM is the most accurate of five models tested

Best model: LightGBM — ROC-AUC 0.703, accuracy 64.1% on unseen customers

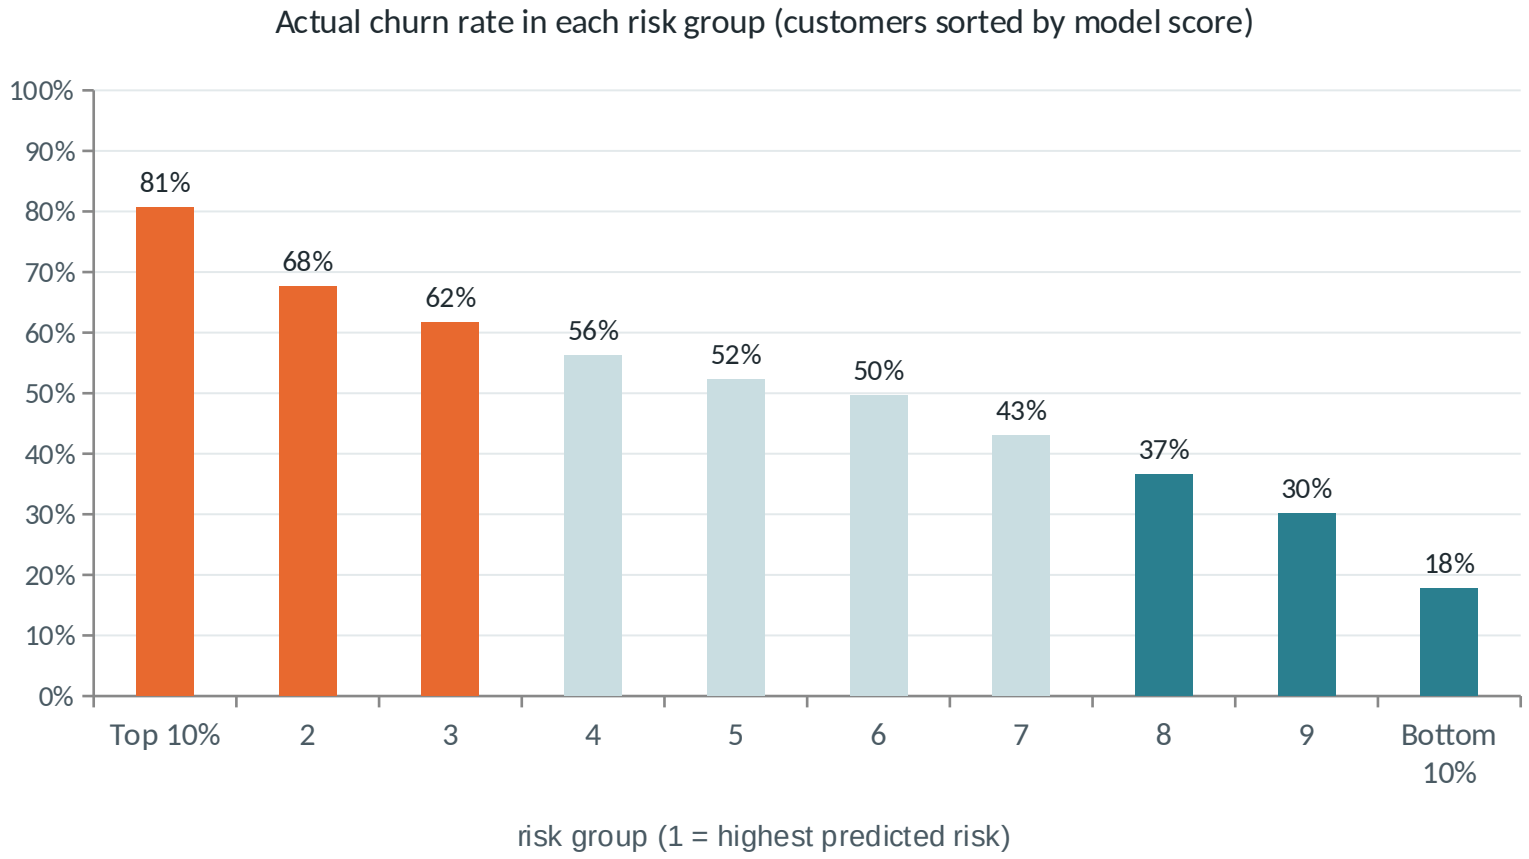

Model	ROC-AUC	Accuracy	F1
LightGBM	**0.703**	**64.1%**	**0.641**
XGBoost	0.700	64.2%	0.641
Random Forest	0.684	62.9%	0.631
Logistic Regression	0.661	61.5%	0.610
No model (guess)	0.500	50.4%	0.000

In plain words: pick one customer who left and one who stayed — the model gives the leaver the higher risk score 70% of the time. Cross-validation gave the same result (0.699 ± 0.003), so it is stable, not luck.

Source: own analysis; 70/30 train/test split, 5-fold cross-validation. AUC ≈ 0.70 is typical for wireless churn data [6] — some churn is driven by events not in the data.

The score finds the customers who will leave

The 10% highest-risk customers churn 4.5× more often than the 10% lowest-risk

80.6%

of the top-10% risk group actually left

42%

of all leavers are in the top 30% — vs 30% if we picked at random

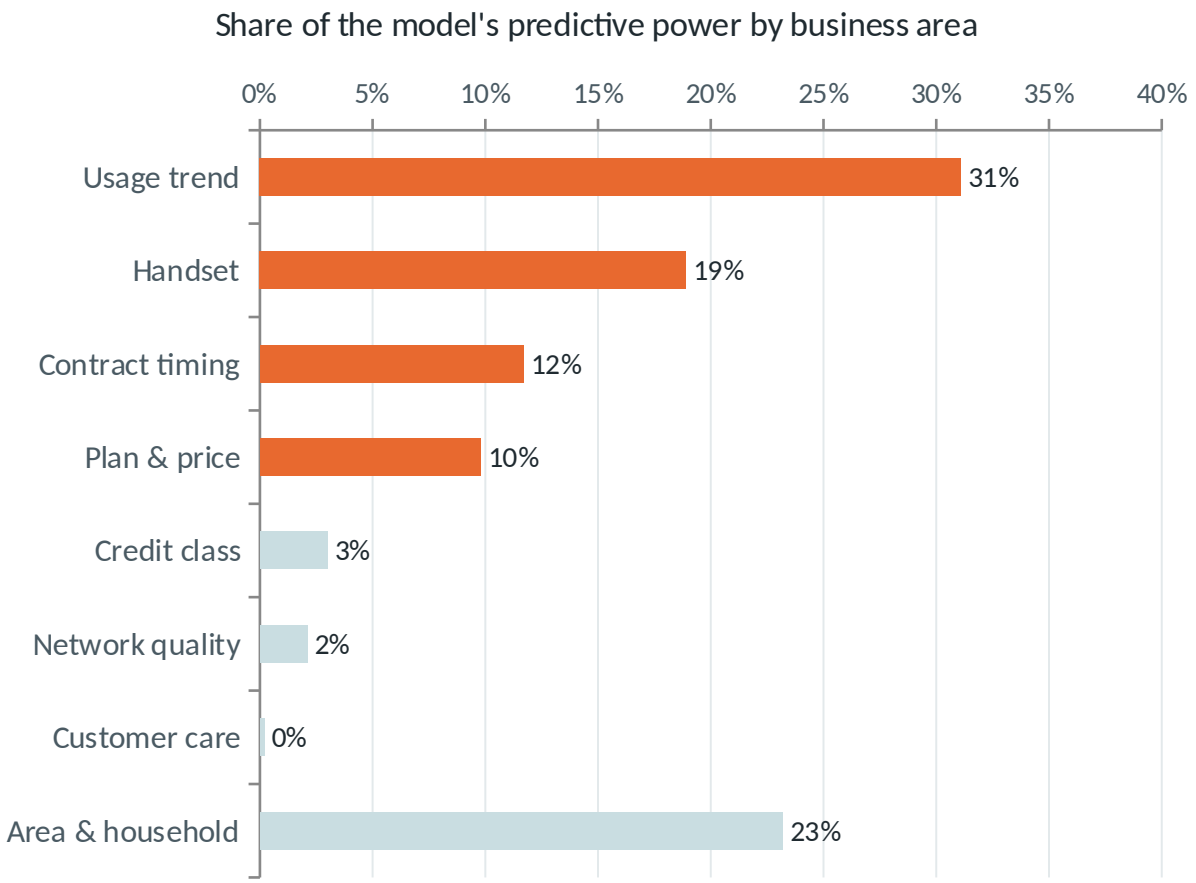

17.8%

churn in the lowest-risk group — no need to spend here

Source: own analysis on 30,000 held-out customers (sample is 50% churners by design).

Why customers leave — and what we can do about it

Two-thirds of the model's knowledge comes from things Company A can act on

Signal → action

Usage trend: Customer uses us less than usual
→ **Proactive call: right-size the plan**

Handset: Handset older than ~1 year
→ **Upgrade offer tied to renewal**

Contract timing: Month 10–13 of tenure
→ **Early-renewal bonus**

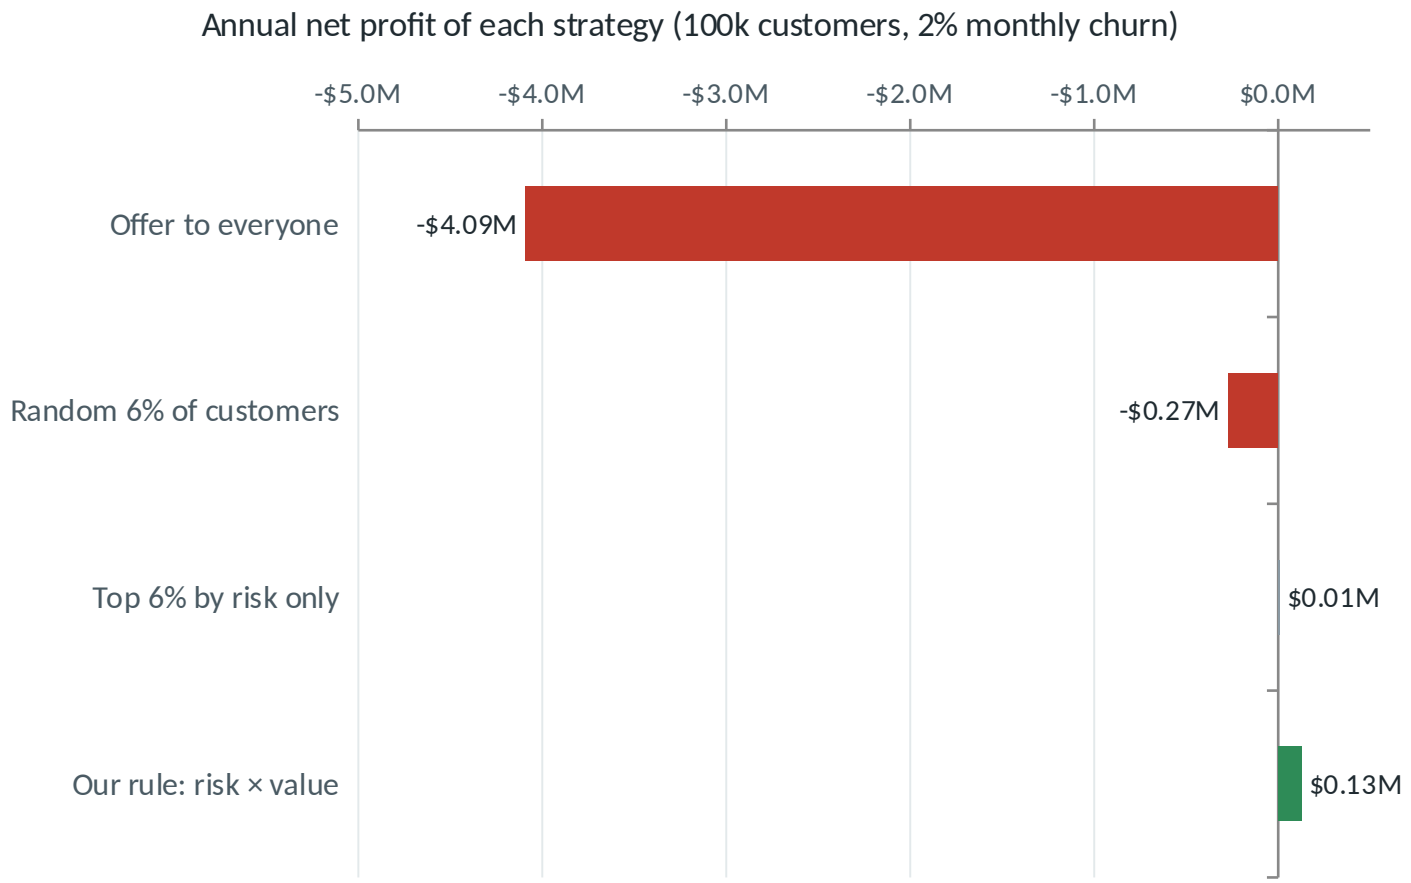

Plan & price: Low monthly plan, cheap handset
→ **Loyalty bundle**

Network quality and customer-care calls add almost nothing — budget should go to handset and plan offers.

Source: own analysis — permutation importance [10] on unseen customers (drop in accuracy when a fact is scrambled). Demographics are not used for targeting decisions.

Who we target decides whether retention pays

Offers to everyone lose millions — targeting risk × customer value turns a profit

Why blanket offers fail

- Only ~2 in 100 customers leave in a month — 98 would have stayed anyway, and many still take the discount.
- The riskiest customers are often low spenders (avg $47/month) — not worth a $25 offer.
- **Our rule picks customers who are both at risk and valuable (avg $134/month).**

Source: own analysis on held-out customers, re-weighted from the 50/50 sample to a 2% monthly churn rate; assumptions on slide 13.

Proposal: a monthly, targeted retention programme

About 3,500 customers a month, each with an offer that fits their reason to leave

Who gets which offer (share of selected customers)

41%	**Upgrade-due:** Handset > 1 year → **Discounted upgrade + 12-month renewal**
28%	**Contract-end:** Month 10–13 → **Early-renewal bonus**
21%	**Other:** High value, other risk → **Loyalty credit**
10%	**Usage-decline:** Usage < 70% of normal → **Plan right-sizing call**

Expected impact per year (base case)

~564 customers kept

$0.83M revenue protected

+$0.13M net profit (ROI 0.64)

Assumptions: 2% monthly churn · 25% of contacted leavers are saved · 15% of stayers also redeem · $25 offer, paid only on renewal · $1 contact (SMS/app) · 40% margin · saved customers stay 12 months

Source: own analysis; impact scaled to 100,000 customers. Assumptions are estimates to be confirmed in the pilot (slide 14).

The result holds up, and grows with a better save rate

Next step: a 3-month pilot to measure what an offer really achieves

Annual net profit under different assumptions ($M, 100k customers)

Saved ↓ · churn →	1.5%/mo	2.0%/mo	3.0%/mo	5.0%/mo
10% saved	$0.00M	$0.01M	$0.03M	$0.13M
20% saved	$0.03M	$0.07M	$0.20M	$0.63M
25% saved	$0.06M	**$0.13M**	$0.32M	$1.00M
30% saved	$0.09M	$0.20M	$0.49M	$1.44M
40% saved	$0.20M	$0.37M	$0.90M	$2.46M

Bold = base case. The rule never loses much: in weak scenarios it simply contacts fewer customers. In more competitive, prepaid-heavy markets (3–5% monthly churn) the value rises to $0.3–1.0M+ a year.

Roadmap

1. **Pilot (months 1–3)**
   Split high-value at-risk customers into offer vs. no-offer groups to measure the true save rate.

2. **Scale (months 4–6)**
   Monthly scoring feeds the CRM and call centre; retrain and monitor every month.

3. **Improve (6+ months)**
   Target customers most likely to respond (uplift model); add complaint and competitor data.

Risks: assumptions not yet measured; the model shows links, not proof of cause; behaviour changes over time. Demographics are excluded from targeting.

Source: own analysis (sensitivity of the expected-value rule; $25 offer). Pilot design follows the profit-driven evaluation of churn models [5].
